Linear Regression

$$MSE = \frac{1}{n} \sum_{i=1}^n (y_i - \hat{f}(x_i))^2$$

- Training error – Performance of model on the previously **seen** data
- Test error – Performance of model on the **unseen** data

Test-Train Split

Linear Regression

Test-Train Split

Training Set - $\{(x_1, y_1), (x_2, y_2), \dots, (x_n, y_n)\}$

Model is trained

$$y = f(x)$$

Test Set - Previously unseen data (x_0, y_0)

Test MSE - $\text{Ave}(\hat{f}(x_0) - y_0)^2$

Other Linear Regression

Test-Train Split

Linear Regression

Test-Train Split Techniques

1. Validation set approach

- Random division of data into two parts
- Usual split is 80:20 (Training : Test)
- When to use – In case of large number of observations

2. Leave one out cross validation

- Leaving one observation every time from training set

3. K-Fold validation

- Divide the data into k set
- We will keep one testing and K-1 for training
